

AI Usage

Which AI tool I used

I used **Claude (by Anthropic)**.

What I used it for

- To turn the assignment document into a working project (folders, scrapers, cleaning, validation, duplicate detection, main.py).
- To write the unit tests.
- To help me fix errors I got while setting up and running the project on Windows.
- To help write the README.

Prompts I used

1. "Give me the Realisieren Technologies assignment in human language, end to end, working in VS Code, simple code that is easy to understand, with correct outputs."
2. "It only edit it and give me a new one, I didn't understand."
3. I also pasted my terminal errors and logs and asked what was wrong.

What the AI did not do

The AI could not open the two websites, so it only tested the code on fake pages. I ran the real scrape myself on my computer.

Problems I found and how I fixed them

- **Wrong folder:** my first setup failed with "requirements.txt not found" because I had extracted the zip inside another copy of the project folder. I extracted it into a new empty folder.
- **pytest errors:** pytest got confused by the two copies of the project. Using a clean folder fixed it, and all 15 tests passed.
- **1099 rows instead of 1100:** my real run removed 1 record as a duplicate, but the code did it silently. I added a log line, and it showed the duplicate was the book "The Star-Touched Queen" (the site lists that title twice). The numbers still match: 1100 raw - 0 rejected - 1 duplicate = 1099 final.
- **Code in the terminal:** I pasted Python code into PowerShell by mistake. Python code must go in the .py file, not the terminal.

How I tested the final code

- `python -m pytest -v` gave **15 passed** (cleaning, validation, duplicates, pagination, a failed page).
- A full `python main.py` run scraped 50 book pages and 10 quote pages in about 61 seconds.
- The summary report shows final = 1099, which matches the number of rows in the CSV.

What I understand about the code

- **Pagination:** the scraper follows the "next" link until there is none, so no page numbers are hard-coded.
- **Failures:** failed requests are retried 3 times, then logged, and only that website stops. A bad record is logged and skipped.

- **Cleaning:** it removes extra spaces, turns "£51.77" into 51.77, and turns "Three" into 3.
- **Duplicates:** it makes a fingerprint from the lowercase text without punctuation or extra spaces, so different spacing or capital letters still match.
